Chapter 4: Threads & Concurrency

Operating System Concepts – 10th Edition

Chapter 4: Threads

- Overview
- Multicore Programming
- Multithreading Models
- Thread Libraries
- Implicit Threading
- Threading Issues
- Operating System Examples

- Identify the basic components of a thread, and contrast threads and processes
- Describe the benefits and challenges of designing multithreaded applications
- Illustrate different approaches to implicit threading including thread pools, fork-join, and Grand Central Dispatch
- Describe how the Windows and Linux operating systems represent threads
- Design multithreaded applications using the Pthreads, Java, and Windows threading APIs

Motivation

- Most modern applications are multithreaded
- Threads run within application
- Multiple tasks with the application can be implemented by separate threads
 - Update display
 - Fetch data
 - Spell checking
 - Answer a network request
- Process creation is heavy-weight while thread creation is light-weight
- Can simplify code, increase efficiency
- Kernels are generally multithreaded

Single and Multithreaded Processes

code	data	files
registers	PC	stack
thread—	• \$	

single-threaded process

multithreaded process

Operating System Concepts – 10th Edition

The unit of dispatching is referred to as a thread or lightweight process

- The unit of resource ownership is referred to as a process or task
- Multithreading The ability of an OS to support multiple, concurrent paths of execution within a single process

Single Threaded Approaches

 A single thread of execution per process, in which the concept of a thread is not recognized, is referred to as a single-threaded approach

MS-DOS is an example

Silberschatz, Galvin and Gagne ©2018

Multithreaded Approaches

- The right half of Figure 4.1 depicts multithreaded approaches
- A Java run-time environment is an example of a system of one process with multiple threads

Figure 4.1 Threads and Processes

Benefits

- Responsiveness may allow continued execution if part of process is blocked, especially important for user interfaces
- Resource Sharing threads share resources of process, easier than shared memory or message passing
- Economy cheaper than process creation, thread switching lower overhead than context switching
- Scalability process can take advantage of multicore architectures

- Multicore or multiprocessor systems putting pressure on programmers, challenges include:
 - Dividing activities
 - Balance
 - Data splitting
 - Data dependency
 - Testing and debugging
- Parallelism implies a system can perform more than one task simultaneously
 - **Concurrency** supports more than one task making progress
 - Single processor / core, scheduler providing concurrency

Concurrent execution on single-core system:

single core

Parallelism on a multi-core system:

Operating System Concepts – 10th Edition

Multicore Programming

Types of parallelism

- Data parallelism distributes subsets of the same data across multiple cores, same operation on each
- Task parallelism distributing threads across cores, each thread performing unique operation

Data and Task Parallelism

Operating System Concepts – 10th Edition

core₁

core₀

core 2

core 3

- Identifies performance gains from adding additional cores to an application that has both serial and parallel components
- S is serial portion
- N processing cores

$$speedup \le \frac{1}{S + \frac{(1-S)}{N}}$$

- That is, if application is 75% parallel / 25% serial, moving from 1 to 2 cores results in speedup of 1.6 times
- As N approaches infinity, speedup approaches 1 / S

Serial portion of an application has disproportionate effect on performance gained by adding additional cores

But does the law take into account contemporary multicore systems?

Amdahl's Law

User Threads and Kernel Threads

- User threads management done by user-level threads library
- Three primary thread libraries:
 - POSIX Pthreads
 - Windows threads
 - Java threads
- Kernel threads Supported by the Kernel
- Examples virtually all general purpose operating systems, including:
 - Windows
 - Linux
 - Mac OS X
 - iOS
 - Android

User and Kernel Threads

Multithreading Models

- Many-to-One
- One-to-One
- Many-to-Many

- Many user-level threads mapped to single kernel thread
- One thread blocking causes all to block
- Multiple threads may not run in parallel on muticore system because only one may be in kernel at a time
 - Few systems currently use this model
- Examples:
 - Solaris Green Threads
 - GNU Portable Threads

One-to-One

- Each user-level thread maps to kernel thread
- Creating a user-level thread creates a kernel thread
- More concurrency than many-to-one
- Number of threads per process sometimes restricted due to overhead
 - Examples
 - Windows
 - Linux

Many-to-Many Model

- Allows many user level threads to be mapped to many kernel threads
- Allows the operating system to create a sufficient number of kernel threads
- Windows with the ThreadFiber package
- Otherwise not very common

Two-level Model

Similar to M:M, except that it allows a user thread to be **bound** to kernel thread

- Thread library provides programmer with API for creating and managing threads
- Two primary ways of implementing
 - Library entirely in user space
 - Kernel-level library supported by the OS

- May be provided either as user-level or kernel-level
- A POSIX standard (IEEE 1003.1c) API for thread creation and synchronization
- Specification, not implementation
- API specifies behavior of the thread library, implementation is up to development of the library
- Common in UNIX operating systems (Linux & Mac OS X)

Pthreads Example

#include <pthread.h>
#include <stdio.h>

```
#include <stdlib.h>
```

```
int sum; /* this data is shared by the thread(s) */
void *runner(void *param); /* threads call this function */
```

```
int main(int argc, char *argv[])
{
   pthread_t tid; /* the thread identifier */
   pthread_attr_t attr; /* set of thread attributes */
   /* set the default attributes of the thread */
   pthread_attr_init(&attr);
   /* create the thread */
   pthread_create(&tid, &attr, runner, argv[1]);
   /* wait for the thread to exit */
   pthread_join(tid,NULL);
```

```
printf("sum = %d\n",sum);
```

}

```
/* The thread will execute in this function */
void *runner(void *param)
{
    int i, upper = atoi(param);
    sum = 0;
    for (i = 1; i <= upper; i++)
        sum += i;
    pthread_exit(0);
}</pre>
```

```
#define NUM_THREADS 10
```

```
/* an array of threads to be joined upon */
pthread_t workers[NUM_THREADS];
```

```
for (int i = 0; i < NUM_THREADS; i++)
    pthread_join(workers[i], NULL);</pre>
```

- Growing in popularity as numbers of threads increase, program correctness more difficult with explicit threads
- Creation and management of threads done by compilers and run-time libraries rather than programmers
- Five methods explored
 - Thread Pools
 - Fork-Join
 - OpenMP
 - Grand Central Dispatch
 - Intel Threading Building Blocks

Operating System Concepts – 10th Edition

Fork-Join Parallelism

Operating System Concepts – 10th Edition

Signal Handling

- **Signals** are used in UNIX systems to notify a process that a particular event has occurred.
- A signal handler is used to process signals
 - 1. Signal is generated by particular event
 - 2. Signal is delivered to a process
 - 3. Signal is handled by one of two signal handlers:
 - 1. default
 - 2. user-defined
- Every signal has default handler that kernel runs when handling signal
 - User-defined signal handler can override default
 - For single-threaded, signal delivered to process

Signal Handling (Cont.)

- Where should a signal be delivered for multi-threaded?
 - Deliver the signal to the thread to which the signal applies
 - Deliver the signal to every thread in the process
 - Deliver the signal to certain threads in the process
 - Assign a specific thread to receive all signals for the process

- Terminating a thread before it has finished
- Thread to be canceled is target thread
- Two general approaches:
 - Asynchronous cancellation terminates the target thread immediately
 - Deferred cancellation allows the target thread to periodically check if it should be cancelled
- Pthread code to create and cancel a thread:

```
pthread_t tid;
/* create the thread */
pthread_create(&tid, 0, worker, NULL);
    . . .
/* cancel the thread */
pthread_cancel(tid);
/* wait for the thread to terminate */
pthread_join(tid,NULL);
```

Invoking thread cancellation requests cancellation, but actual cancellation depends on thread state

Mode	State	Туре
Off	Disabled	_
Deferred	Enabled	Deferred
Asynchronous	Enabled	Asynchronous

- If thread has cancellation disabled, cancellation remains pending until thread enables it
- Default type is deferred
 - Cancellation only occurs when thread reaches cancellation point
 - > l.e. pthread_testcancel()
 - Then cleanup handler is invoked
- On Linux systems, thread cancellation is handled through signals

Silberschatz, Galvin and Gagne ©2018

Thread-Local Storage

- Thread-local storage (TLS) allows each thread to have its own copy of data
- Useful when you do not have control over the thread creation process (i.e., when using a thread pool)
- Different from local variables
 - Local variables visible only during single function invocation
 - TLS visible across function invocations
- Similar to static data
 - TLS is unique to each thread

Operating System Examples

Linux Threads

- Linux refers to them as *tasks* rather than *threads*
- Thread creation is done through clone() system call
- clone() allows a child task to share the address space of the parent task (process)
 - Flags control behavior

flag	meaning
CLONE_FS	File-system information is shared.
CLONE_VM	The same memory space is shared.
CLONE_SIGHAND	Signal handlers are shared.
CLONE_FILES	The set of open files is shared.

struct task_struct points to process data structures (shared or unique)

End of Chapter 4
